BCEA Annual Conference

Sofia University, June 24, 2025

The views expressed here are the responsibility of the authors only, and do not necessarily coincide with those of the ECB or the Eurosystem.

Motivation

• Recent events have brought new evidence regarding the drivers and dynamics of inflation:

- i Possibility of large inflationary swings in advanced economies

 Challenge: NKPC with a realistic slope requires implausibly large shocks (L'Huillier and Phelan, 2024)

 ii Fluctuations in the frequency of price adjustment (Montag and Villar, 2023; Cavallo et al., 2024)

 Challenge: a fixed menu cost model matches that at the cost of an implausibly steep NKPC (Blanco et al., 2024)

 iii Importance of sector-specific drivers of inflation (Schneider, 2023; Rubbo, 2024)

 Challenge: need to allow for large sector-specific shocks in a setting with menu costs
- Develop a dynamic quantitative general equilibrium model that features: a number of sectors interconnected by networks with state-dependent pricing that is solved fully non-linearly

New cyclical mechanism: interaction of **networks** and pricing **cascades**

- **Interaction** of our model ingredients creates pricing **cascades**: large movements in aggregates trigger additional price adjustment decisions at the extensive margin
- Demand shocks Networks slow down the extensive margin adjustment: cascades dampening
 - i Networks slow down the desired price changes, hence firms are less willing to pay the cost of adjustment
 - ii Quantitatively, delivers a "global flattening" of the Phillips Curve, implying strong monetary non-neutrality even following very large shocks
- Supply shocks (Agg./sectoral) Networks speed up the extensive margin adjust.: cascades amplification
 - i Networks amplify the desired price changes, hence firms are more willing to pay the cost of adjustment
 - ii Quantitatively, creates frequency increases and inflationary spirals following aggregate TFP/markup shocks, or TFP/markup shocks to sectors that are major suppliers to the rest of the economy

Model overview

• **Timing**: infinite-horizon setting in discrete time, indexed by t = 0, 1, 2, ...

• Households: continuum of identical households; consume output and supply labor

• Firms: continuum of monopolistically competitive firms, each belongs to one of N sectors, indexed $i \in \{1, 2, ..., N\}$; there is a measure one of firms in each sector

• Factors: firms use labor and intermediate inputs purchased from other firms

• **Government Policy**: central bank sets the level of money supply M_t

Households

• The representative household maximizes expected lifetime utility:

$$\mathbb{E}_0 \sum_{t=0}^{\infty} \beta^t \left[\log C_t - L_t \right]$$

subject to a standard budget constraint

- Households are also subject to a **cash-in-advance** constraint: $P_t^C C_t \le M_t$
- Aggregate consumption: $C_t = \iota^C \prod_{i=1}^N C_i^{\overline{\omega}_i^C}, \quad \sum_{i=1}^N \overline{\omega}_i^C = 1, \quad \overline{\omega}_i^C \ge 0, \forall i$
- Sectoral consumption: $C_{i,t} = \left\{ \int_0^1 \left[\zeta_{i,t}(j) C_{i,t}(j) \right]^{\frac{\epsilon 1}{\epsilon}} dj \right\}^{\frac{\epsilon}{\epsilon 1}}, \quad \epsilon > 1$ where $\zeta_{i,t}(j)$ is a **firm-level quality** process:

$$\log \zeta_{i,t}(j) = \log \zeta_{i,t-1}(j) + \sigma_i \varepsilon_{i,t}(j)$$

Firms: production

• Any firm *j* in sector *i* has access to the following production technology:

$$Y_{i,t}(j) = \iota_i \frac{1}{\zeta_{i,t}(j)} \times A_{i,t} \times L_{i,t}(j)^{\overline{\alpha}_i} \prod_{k=1}^N X_{i,k,t}(j)^{\overline{\omega}_{ik}},$$

where $A_{i,t}$ is a **sectoral productivity** process, $L_{i,t}(j)$ is firm-level labor input, $X_{i,k,t}(j)$ is firm-level intermediate input demand for sector k's goods and $\overline{\alpha}_i + \sum_{k=1}^N \overline{\omega}_{ik} = 1$, $\overline{\alpha}_i \geq 0$, $\overline{\omega}_{ik} \geq 0$, $\forall i, k$

• Cost-minimization delivers the following real marginal cost:

$$MC_{i,t}(j) = \zeta_{i,t}(j) \times \frac{M_t}{A_{i,t}} \times \prod_{k=1}^{N} \frac{P_{k,t}^{\omega_{ik}}}{M_t}$$

Firms: pricing

• Price resetting involves paying a sector-specific **menu cost** $\kappa_{i,t}$ measured in labor hours

- Let $p_{i,t}(j) \equiv \log \tilde{P}_{i,t}(j) = \log \frac{P_{i,t}(j)}{\zeta_{i,t}(j)M_t}$ be the quality-adjusted \log real price
- The value of a firm in sector *i* that has set a quality-adjusted real price *p*:

$$V_{i,t}(p) = \tilde{\mathcal{D}}_{i,t}(p) + \beta \mathbb{E}_t \left[\left\{ 1 - \eta_{i,t+1} \left(p - \sigma_i \varepsilon_{i,t+1} - m_{t+1} \right) \right\} \times V_{i,t+1} \underbrace{\left(p - \sigma_i \varepsilon_{i,t+1} - m_{t+1} \right)}^{\text{"Eroded" real price}} \right] \right]$$

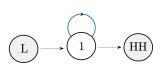

$$+\beta \mathbb{E}_{t} \left[\underbrace{\eta_{i,t+1} \left(p - \sigma_{i} \varepsilon_{i,t+1} - m_{t+1} \right)}_{\text{Pr. of adjustment}} \times \left(\max_{p'} V_{i,t+1} \left(p' \right) - \kappa_{i,t} \right) \right]$$

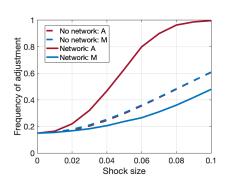

• Following Golosov and Lucas (2007), we assume the following **adjustment hazard** $\eta_{i,t}(.)$:

$$\eta_{i,t}(p) = \mathbf{1}(L_{i,t}(p) > 0) = \mathbf{1}\left(\max_{p'} V_{i,t}\left(p'\right) - V_{i,t}(p) > \overline{\kappa}_i\right)$$

Toy example 1: roundabout production

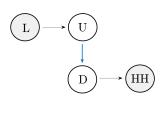

• Marginal cost:
$$MC(j) = \zeta(j) \times \frac{1}{A} \times M^{\overline{\alpha}} P^{1-\overline{\alpha}} = \zeta(j) \times \frac{M}{A} \times \left(\frac{P}{M}\right)^{1-\overline{\alpha}}$$

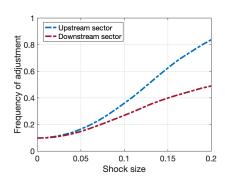

Toy example 2: two-sector vertical chain

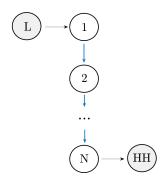

• Marginal costs: $MC_U(j) = \zeta_U(j) \times \frac{1}{A_U} \times M$, $MC_D(j) = \zeta_D(j) \times \frac{1}{A_D} \times P_U$

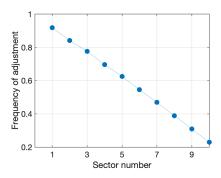

Toy example 3: *N*-sector vertical chain

• Marginal costs: $MC_i(j) = \zeta_i(j) \times \frac{1}{A_i} \times P_{i-1}$

Computation

- Steady state: solve the stationary Bellman equations and firms' price distribution on an evenly spaced grid of log quality-adjusted real prices for every sector
- Consider a **known** sequence of money supply $\{\Delta \log M_t\}_{t=0}^{\infty}$ and productivity $\{\log A_{k,t}\}_{t=0}^{\infty}$
- Assume that after a finite time period T the economy converges back to the stationary distribution
- From a guess for the sequences of aggregate and sectoral variables, follow backward-forward iteration until convergence:
 - ① Starting from t = T, iterate **backwards** to t = 0 to solve for the micro value functions
 - ② Starting from t = 0, iterate **forwards** to t = T to solve for price distributions and aggregate numerically

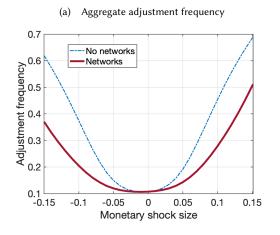

Calibration (Euro Area, monthly frequency)

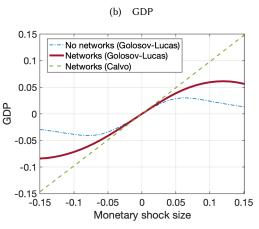

Aggregate parameters			
β	0.96 ^{1/12}	Discount factor (monthly)	Golosov and Lucas (2007)
ϵ	3	Goods elasticity of substitution	Midrigan (2011)
$\overline{\pi}$	0.02/12	Trend inflation (monthly)	ECB target
ho	0.90	Persistence of the TFP shock	Half-life of seven months
Sectoral parameters			
N	39	Number of sectors	Data from Gautier et al. (2024)
$\{\overline{\omega}_i^C\}_{i=1}^N$		Sector consumption weights	World IO Tables
$\{\overline{\omega}_{ik}\}_{i,k=1}^{N}$		Sector input-output matrix	World IO Tables
$\{\overline{\alpha}_i\}_{i=1}^N$		Sector labor weights	World IO Tables
Firm-level pricing parameters			
$\{\overline{\kappa}_i\}_{i=1}^N$		Menu costs	Estimated to fit frequency, std dev.
$\{\sigma_i\}_{i=1}^N$		Std. dev. of firm-level shocks	of Δp from Gautier et al. (2024)

Monetary shocks

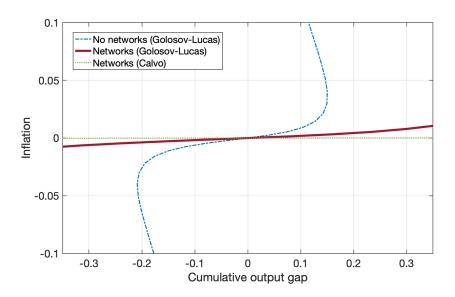

$$\log M_t = \overline{\pi} + \log M_{t-1} + \varepsilon_t^M$$

Cascades dampening following monetary shocks

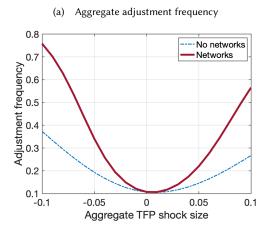

Non-linear Phillips Curves

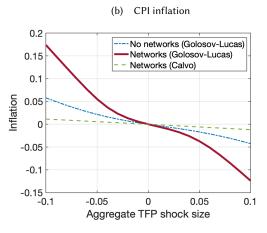

Aggregate TFP shocks

$$\log A_t = \rho \log A_{t-1} + \varepsilon_t^A$$

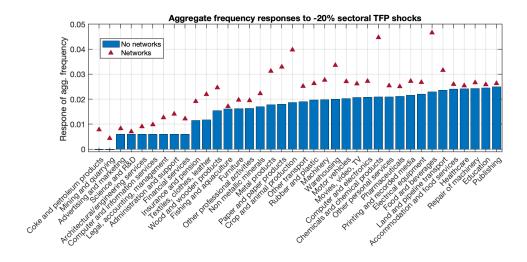

Cascades amplification following TFP shocks

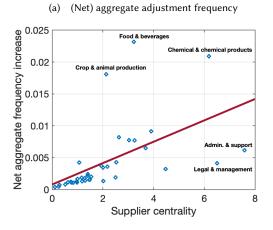

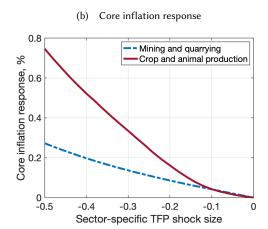

Sectoral TFP shocks

Aggregate frequency responses to sectoral TFP shocks (-20%)

Aggregate frequency responses vs. sectoral Supplier Centrality

Model vs. Data

• To assess the model quantitatively, we feed in observed demand and supply processes as exogenous shocks

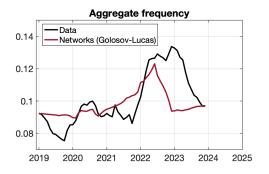

• **Aggregate demand shock**: Euro Area nominal GDP as a proxy for the $\{M_t\}_{t\geq 0}$ process

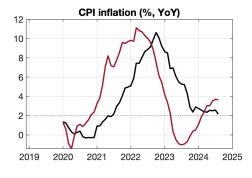

• Energy price shock: calibrate the productivity process of the "Mining and Quarrying" sector to match the IMF Global Price of Energy Index movements

• Food price shock: calibrate the productivity process of the "Crop and Animal Production" sector to match the IMF Global Price of Food Index movements

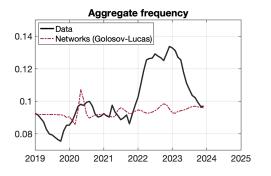

• Labor market shock: calibrate the productivity process of the labor union sector to match the hourly earnings dynamics in the Euro Area

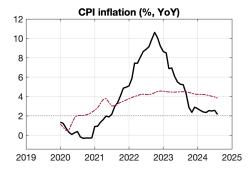

Model vs. Data: baseline setup, all shocks

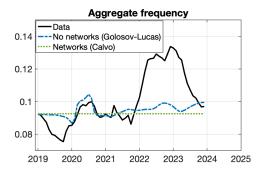

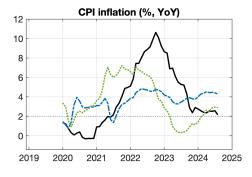

Model vs. Data: baseline setup, no commodity shocks

Model vs. Data: alternative setups, all shocks

Conclusions

Present a dynamic quantitative general equilibrium model that features: a number of sectors interconnected
 by networks with state-dependent pricing that is solved fully non-linearly

Networks slow down the extensive margin pricing response to demand shocks: cascades dampening

• Networks speed up the extensive margin response to supply shocks: cascades amplification

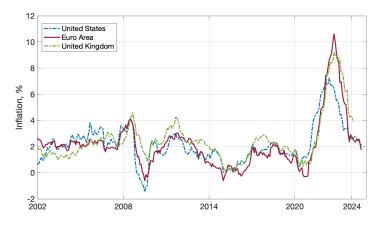

• Interaction of networks and pricing cascades crucial for quantitatively matching the observed surges in inflation and repricing frequency in the Euro Area
